Flag question
Consider the following relations in a database created for a university.
Module (mCode: char(6), mName: varchar (50), credits: int, specialization: char (4), year: int, semester: int)
Student (sid: char(I0), sName: varchar(50), age: int, gpa: int, address: varchar(50))
Follow (sId: char(IO), mCode: char(6), semester: int, academicYear: int, grade: char(1))
Class (cId: int, mCode: char(6), sId: Char(I0), type: varchar(I0), day: char(3), time:time, length: int, hId: char(4))
Hall (hId: char(4), building: varchar(I5), floorNo: int, capacity: int)
Module relation stores the module code, name, number of credits, and the specialization the module belongs to (such as 'IT', 'SE', 'CSN'), year and the semester of the module.
Student relation stores the ID, name, age, cumulative gpa, and address of all students.
For each student following a module in the university the Follow relation stores the ID of the student, code of the module, the semester the module is offered (such as 1 and 2), the academic year the student has followed the module (such as 2018 and 2019) and the grade he received for the module.
The Class relation stores the id , code, type of the class (such as 'lecture' and 'tutorial'), day the class is conducted such as ('Mon', "Tue', 'Wed'), start time of the class, length of the class in hours, and the id of the hall the class is conducted.
Hall relation stores the ID, name of the building the hall is in, floor number the hall is in, and capacity of each Hall.
Create a function named 'getAvailability' which takes class id and module code as inputs and returns the number of more students that could be added to the class based on class size and the capacity of the hall.

Consider the following relations of a database created for a car insurance company.
Driver (drivingLNo: char(4), name: varchar(20), address: varchar(50), phone: char(10))
Car (regNo: char(5), make: varchar (20), model: varchar (20), year: date, driveLNo: char(4))
Accident (accidentNo: varchar(20), location: varchar(50), accidentDate: datetime)
Car_Accident (regNo : char(5), accNo: varchar(20), accidentDate: datetime)
Claim (regNo: char(18), accNo: varchar(20), driveLNo: char(4), claimDate: datetime, claimAmt:real)
The database stores information on drivers registered by the car insurance company in the Driver table. The table stores a unique driving license number (drivingLNo), name, address and the phone number. Information about the cars is recorded in the Car table. The table includes a registration number(regNo), make ('Toyota', 'Ford', 'Audi', etc.), model ('Aqua', 'Axio' etc.), manufactured year and the owner of the car using the license number (driveLNo). When a Driver met with an accident, the company stores the records in an Accident table along with the unique number (accidentNo), location of the accident (location) and the time the accident happened (accidentDate). To keep track of all the accidents a Car_Accident table is listed with regNo, accident number and the date the accident happened. When a driver request for a claim the entries will be inserted to a Claim table following the regNo, accident number, driver number, claim date and claim amount.
Create a procedure which calculates the total claim amount for a given vehicle for a given year.

Consider the following relations of a database created for a car insurance company.
Driver (drivingLNo: char(4), name: varchar(20), address: varchar(50), phone: char(10))
Car (regNo: char(5), make: varchar (20), model: varchar (20), year: date, driveLNo: char(4))
Accident (accidentNo: varchar(20), location: varchar(50), accidentDate: datetime)
Car_Accident (regNo : char(5), accNo: varchar(20), accidentDate: datetime)
Claim (regNo: char(18), accNo: varchar(20), driveLNo: char(4), claimDate: datetime, claimAmt:real)
The database stores information on drivers registered by the car insurance company in the Driver table. The table stores a unique driving license number (drivingLNo), name, address and the phone number. Information about the cars is recorded in the Car table. The table includes a registration number(regNo), make ('Toyota', 'Ford', 'Audi', etc.), model ('Aqua', 'Axio' etc.), manufactured year and the owner of the car using the license number (driveLNo). When a Driver met with an accident, the company stores the records in an Accident table along with the unique number (accidentNo), location of the accident (location) and the time the accident happened (accidentDate). To keep track of all the accidents a Car_Accident table is listed with regNo, accident number and the date the accident happened. When a driver request for a claim the entries will be inserted to a Claim table following the regNo, accident number, driver number, claim date and claim amount.
Create a function which calculates the number of accidents met by a given driver in a given year.

Consider the following relations of a database created for a car insurance company.
Driver (drivingLNo: char(4), name: varchar(20), address: varchar(50), phone: char(10))
Car (regNo: char(5), make: varchar (20), model: varchar (20), year: date, driveLNo: char(4))
Accident (accidentNo: varchar(20), location: varchar(50), accidentDate: datetime)
Car_Accident (regNo : char(5), accNo: varchar(20), accidentDate: datetime)
Claim (regNo: char(18), accNo: varchar(20), driveLNo: char(4), claimDate: datetime, claimAmt:real)
The database stores information on drivers registered by the car insurance company in the Driver table. The table stores a unique driving license number (drivingLNo), name, address and the phone number. Information about the cars is recorded in the Car table. The table includes a registration number(regNo), make ('Toyota', 'Ford', 'Audi', etc.), model ('Aqua', 'Axio' etc.), manufactured year and the owner of the car using the license number (driveLNo). When a Driver met with an accident, the company stores the records in an Accident table along with the unique number (accidentNo), location of the accident (location) and the time the accident happened (accidentDate). To keep track of all the accidents a Car_Accident table is listed with regNo, accident number and the date the accident happened. When a driver request for a claim the entries will be inserted to a Claim table following the regNo, accident number, driver number, claim date and claim amount.
Assume that the insurance company accepts claims only within 10 days from the date of the accident. Create a stored procedure to output the status (whether the claim is accepted or rejected) of the claim given the registration number and the accident number.

Which of the following is/are true related to triggers
Select one or more:
a. SQL server Triggers only respond to insert, update and delete operations.
b. In instead of triggers, trigger is executed before the table is updated
c. A for trigger execute after the operation(insert ,update ,delete) has taken place in the table
d. The for clause specifies the table name on which the trigger is to be attached
e. Triggers are useful for auditing and imposing business logic

Given the following statements:

```
CREATE TABLE tbl (col1 INTEGER, col2 CHAR(5));
CREATE TABLE tblAudit (user VARCHAR(20), date DATE, action VARCHAR(20));
CREATE TRIGGER trig_tblAudit ON tbl FOR INSERT AS
BEGIN
INSERT INTO tblAudit VALUES (CURRENT USER, CURRENT DATE,'Insert');
END
```

If user USER1 executes the following statements:

```
INSERT INTO tbl VALUES (1, 'abc');
INSERT INTO tbl (col1) VALUES (2);
UPDATE tbl SET col2 = 'Hacked' WHERE col1 = 1;
```

How many new records will be written to the database tables?

Select one:

- a. 4
- b. 5
- c. 0
- d. 3
- e. 2

Given the following statements:

```
CREATE TABLE tbl (col1 INTEGER, col2 CHAR(5));
CREATE TABLE tblAudit (user VARCHAR(20), date DATE, action VARCHAR(20));
CREATE TRIGGER trig_tblAudit ON tbl FOR INSERT AS
BEGIN
INSERT INTO tblAudit VALUES (CURRENT USER, CURRENT DATE,'Insert');
END
```

If user USER1 executes the following statements:

Consider the following relations of a database created for a **Car Rental** company.

Driver (driverID: char(4), driver_name: varchar(15), address: varchar(50), phone: char(10), licenceNo: char(5))

Car (carID: char(4), make: varchar(15), model: varchar(15), body_type: varchar(15), no_seats: int, year: datetime)

Route (route_id: char(4), source: varchar(20), destination: varchar(20), route_type: varchar(15), fare: real)

Customer (customerID: char(4), customer_name: varchar(20), phone: char(10), address: varchar(50))

Booking (booking_id: char(4), dateBooked: datetime, dateReturned: datetime, customerID: char(4), route_id: char(4), car_id: char(4), driverID: char(4))

The database stores information on Divers registered by the car rental company in the **Driver** table. The table stores a unique driver ID (driverID), name, address, phone number and the driving license number. Information about the Cars is recorded in the **Car** table. The table includes a unique number (carID), make ('Toyota', 'Honda', 'Audi', etc.), model ('Aqua', 'Civic' etc.), body type ('Wagon', 'Hatchback' etc.), number of seats, and the year manufactured. **Route** table stores all the operations on car routes including a unique number (route_id), route source, route destination, route type ('one way' or 'both ways') and the fare amount. Information about the Customers is also documented in the **Customer** table. The table consists of a unique number (customerID), customer name, phone number and address. When a Customer wants to rent a car the company stores the records in a **Booking** table along with the unique number (booking_id), date of which the booking happened, the return date of the car, the customer who elaborate in renting the car (customberID), the route in which the car is traveling (route_id), the car ID (car_id) and the driver who is dedicated for driving the car (driverID).

Create a trigger to update the noOfRoutes of a driver when adding a new record to the Booking table. Assume that there exists a stored procedure to update the total number of routes (noOfRoutes) of a driver based on the route entries recorded in the Booking table. The Driver table is modified by adding a new attribute (noOfRoutes: int).

Consider the following relations of a database created for a Car Rental company.

Driver (driverID: char(4), driver_name: varchar(15), address: varchar(50), phone: char(10), licenceNo: char(5))

Car (carID: char(4), make: varchar(15), model: varchar(15), body_type: varchar(15), no_seats: int, year: datetime)

Route (route_id: char(4), source: varchar(20), destination: varchar(20), route_type: varchar(15), fare: real)

Customer (customerID: char(4), customer_name: varchar(20), phone: char(10), address: varchar(50))

Booking (booking_id: char(4), dateBooked: datetime, dateReturned: datetime, customerID: char(4), route_id: char(4), car_id: char(4), driverID: char(4))

The database stores information on Divers registered by the car rental company in the Driver table. The table stores a unique driver ID (driverID), name, address, phone number and the driving license number. Information about the Cars is recorded in the Car table. The table includes a unique number (carID), make ('Toyota', 'Honda', 'Audi', etc.), model ('Aqua', 'Civic' etc.), body type ('Wagon', 'Hatchback' etc.), number of seats, and the year manufactured. Route table stores all the operations on car routes including a unique number (route_id), route source, route destination, route type ('one way' or 'both ways') and the fare amount. Information about the Customers is also documented in the Customer table. The table consists of a unique number (customerID), customer name, phone number and address. When a Customer wants to rent a car the company stores the records in a Booking table along with the unique number (booking_id), date of which the booking happened, the return date of the car, the customer who elaborate in renting the car (customberID), the route in which the car is traveling (route_id), the car ID (car_id) and the driver who is dedicated for driving the car (driverID).

Assume that the company requests to record the number of routes each driver travels. The Driver table is modified by adding a new attribute (noOfRoutes: int), write a query to add the new attribute to the Driver table assuming that the table is already created. Then create a stored procedure to update the total number of routes (noOfRoutes) of a driver based on the route entries recorded in the Booking table. You need to display the driver name who met with the total number of routes.

Given the following class definitions

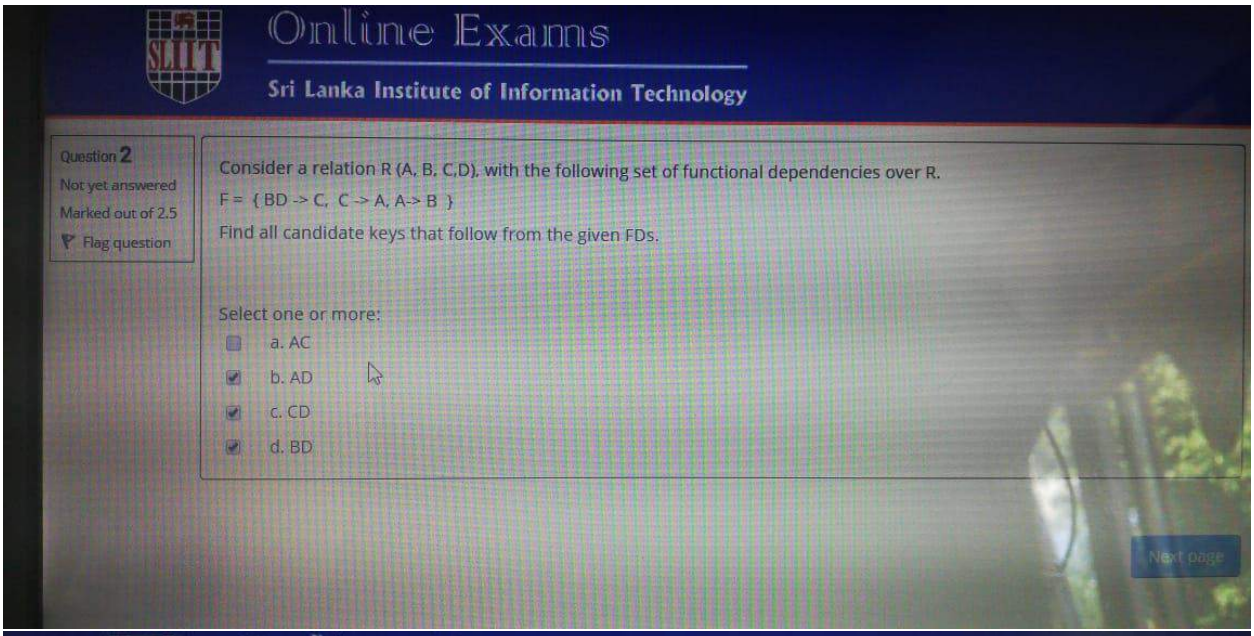

```
1  public class Parent {
2          protected void sayHi() {
3              System.out.print("Hi");
4          }
5  }
6
7  class Child extends Parent {
8          public void sayHi() {
9              System.out.print("Hello");
10     }
11 }
```

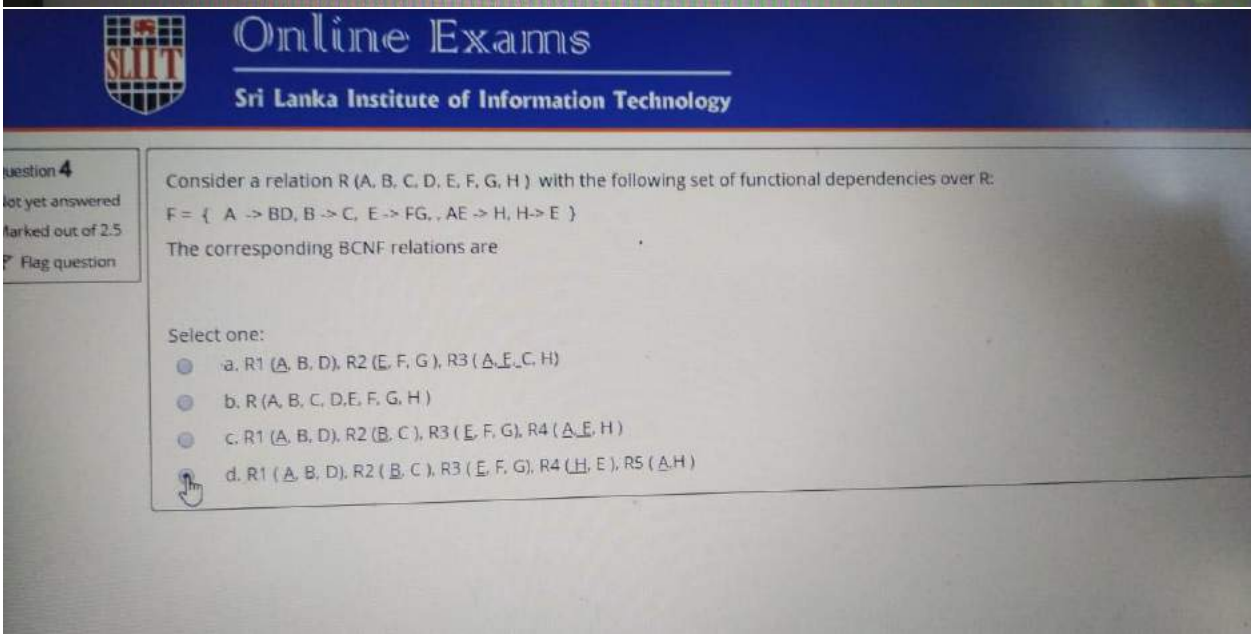

Parent p = new Child();

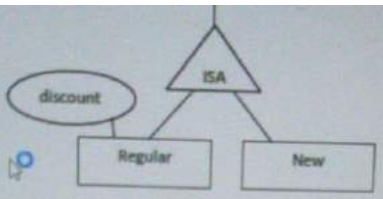

p.sayHi();

Consider the following relations of a database created for a **video rental** company.

Customer (customerID: char(4), *fname*: varchar(20), *lname*: varchar(20), *address*: varchar(50), *phone*: char(10))

Actor (*actorID*: char(4), *actorName*: varchar(30), gender : char(1), age: int)

ActorAward (actorID: char(4), movieID: int, awardName: varchar(25), status: char(15))

AppearsIn (movieID :int, actorID: char(4), *characterName*: varchar(20), role: varchar(15))

Producer (producerID: char(4), *producerName*: varchar(30), *companyName*: varchar (20), *country*: varchar (20))

Moive (movieID: int, *title*: varchar(50), *language*: varchar(10), *duration*: time, *rating*: int, ryear: date,

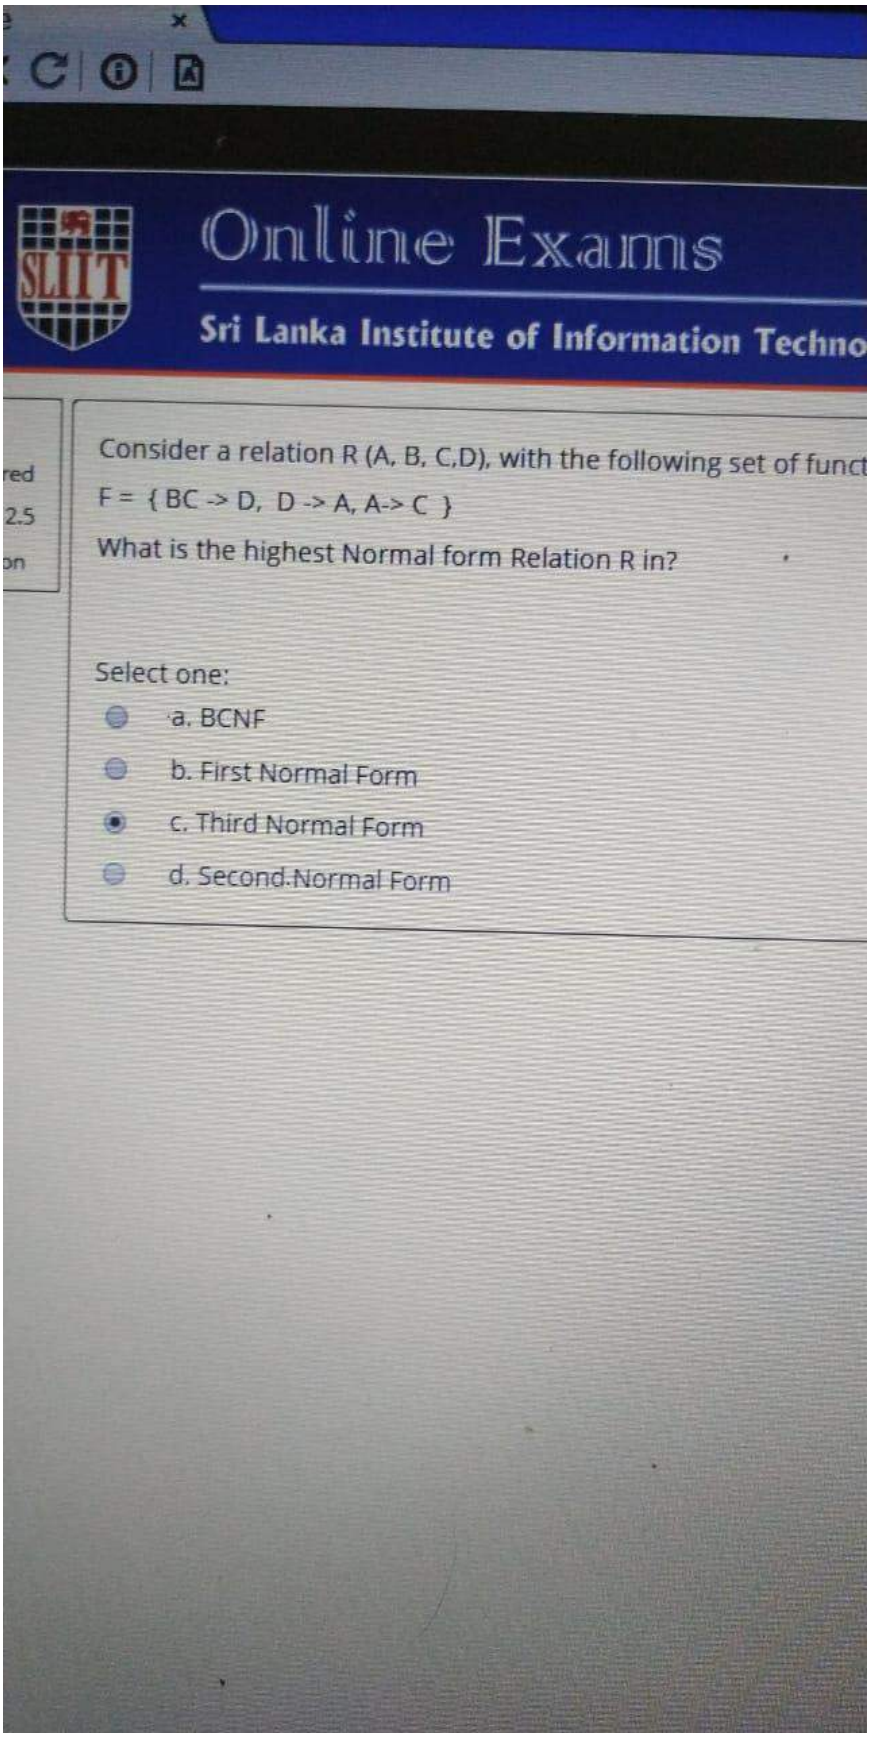

type: varchar(20), *prodId*: char(4))

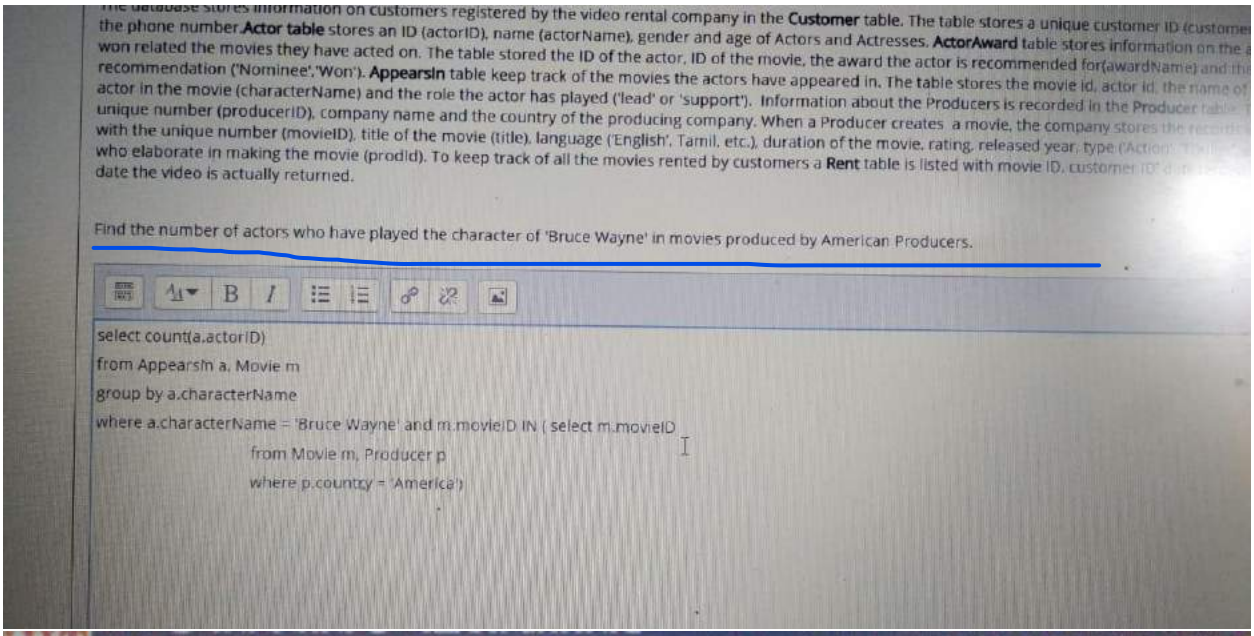

Rent (*mid*: int, cID: char(4), *date_rented*: datetime, *due_rented*: datetime, *date_returned*: datetinie)

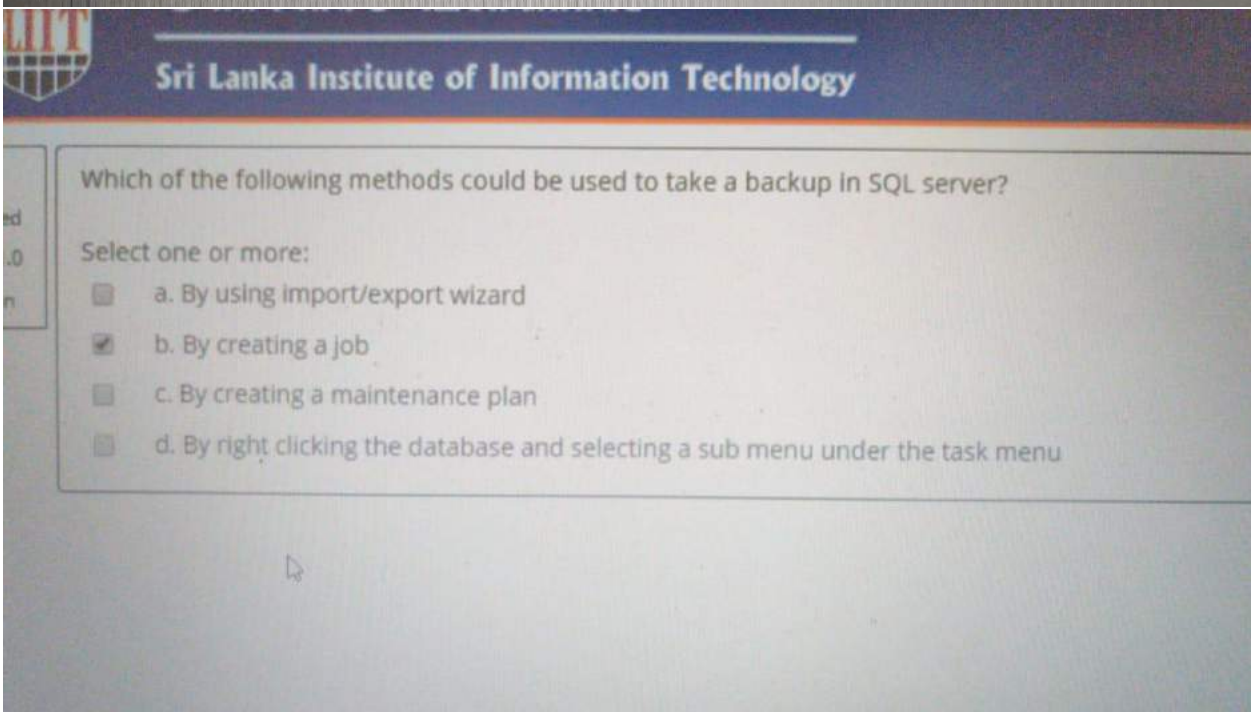

The database stores information on customers registered by the video rental company in the **Customer** table. The table stores a unique customer ID (customerID), name, address and the phone number. **Actor table** stores an ID (actorID), name (actorName), gender and age of Actors and Actresses. **ActorAward** table stores information on the awards the actors have won related the movies they have acted on. The table stored the ID of the actor, ID of the movie, the award the actor is recommended for(awardName) and the status of the recommendation ('Nominee','Won'). **AppearsIn** table keep track of the movies the actors have appeared in. The table stores the movie id, actor id, the name of the character of the actor in the movie (characterName) and the role the actor has played ('lead' or 'support'). Information about the Producers is recorded in the **Producer** table. The table includes a unique number (producerID), company name and the country of the producing company. When a Producer creates a movie, the company stores the records in a **Movie** table along with the unique number (movieID), title of the movie (title), language ('English', Tamil, etc.), duration of the movie, rating, released year, type ('Action', 'Thriller', etc.) and the producer who elaborate in making the movie (prodId). To keep track of all the movies rented by customers a **Rent** table is listed with movie ID, customer ID, date rented , the due date and the date the video is actually returned.

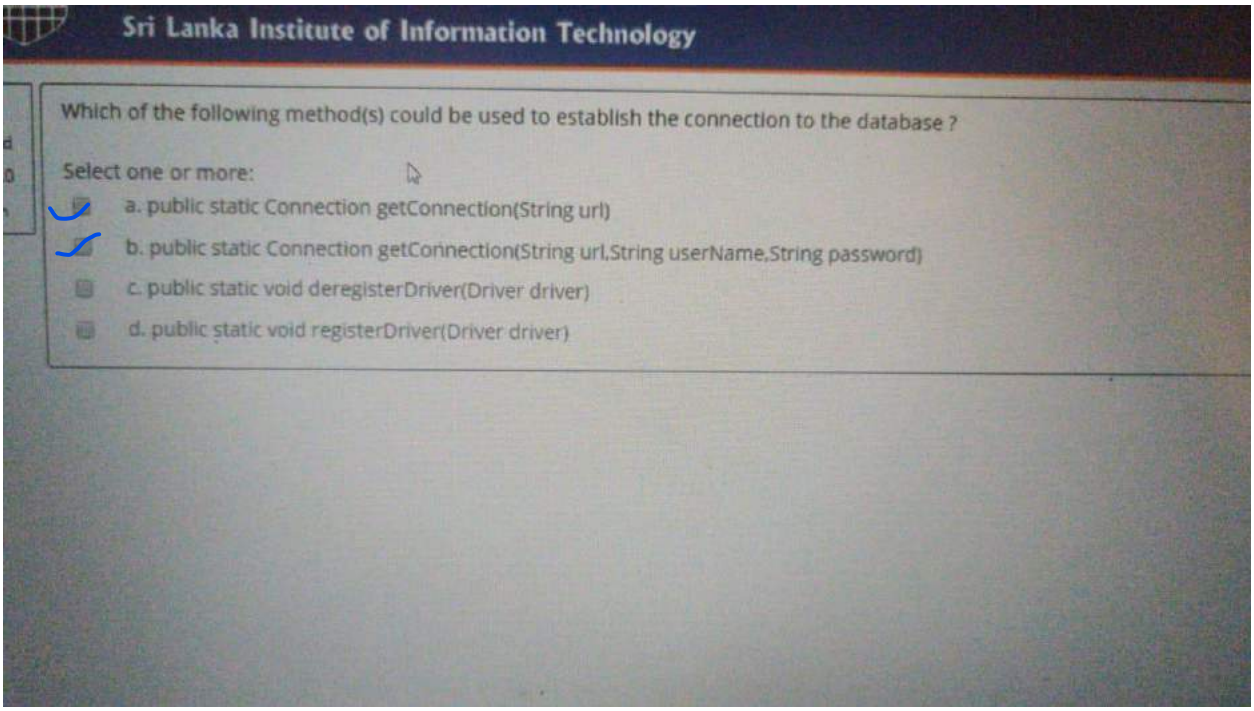

Find the title and the duration of the highest rated movie which is produced by the company 'Century Fox'

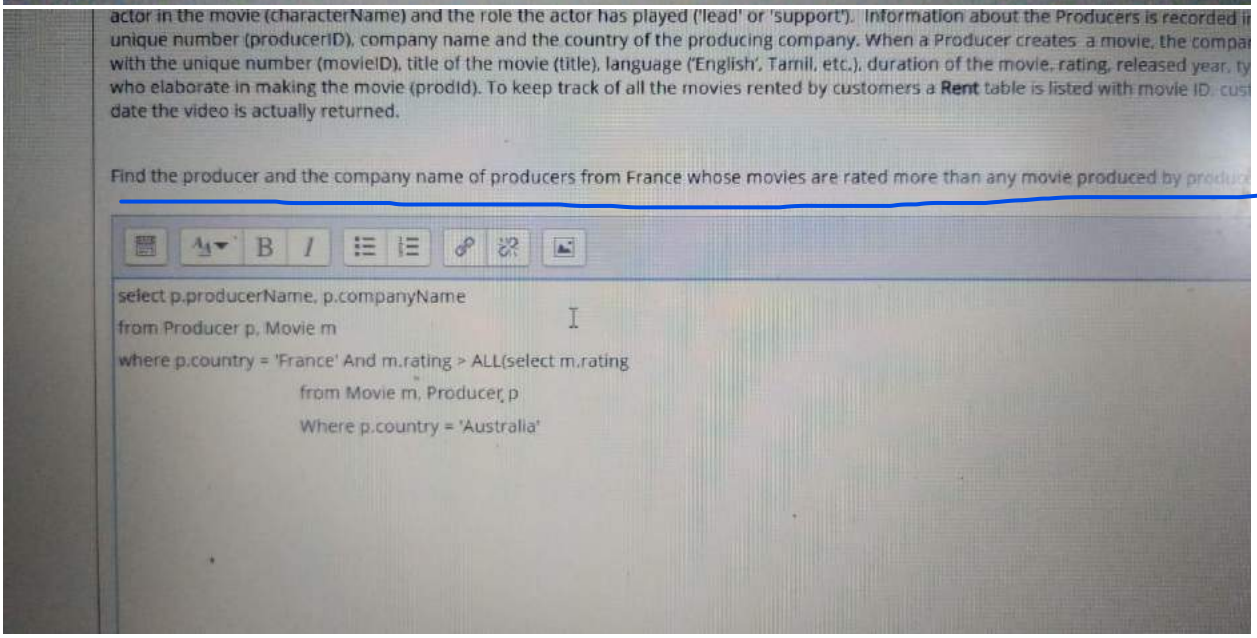

```
select m.title, m.duration, max(m.rating) as 'Rating'

Consider the following scenario:
A software company has been assigned with the responsibility of automating the tasks of a private bank. This include developing a database to record customer details, and an account details. Sunil, a senior DBA is assigned to the project to handle all the administrative tasks related to the databases by the database architect. Sunil creates the required databases and assigned Malika the responsibility of managing the bankDB. Malika assigns Keshan with the responsibility of creating tables. In addition, Keshan should be able to create views, stored procedures and triggers required. Asanka and Ferosh, who are data entry operators are given the responsibility of inserting the data to the table. Nihal is assigned with the responsibility of generating reports from the table in the data. For the above purpose, Nihal could directly query the data or call functions and procedures.
Which of the following/s should you need to provide the necessary permission to Asanka and Ferosh assuming that their usernames are asanka.n and Ferosh.a respectively
Select one or more:
a. ALTER ROLE dataEntry ADD MEMBER asanka.n
b. ALTER ROLE db_owner add member ferosh.a
c. GRANT INSERT on bankDB to dataEntry
d. ALTER ROLE dataEntry ADD MEMBER Ferosh.a
e. ALTER ROLE db_owner add member asanka.n

How can a DML statement (i.e. insert, delete, update) executed in the database?
Select one:
a. By making use of the execute() statement of the DMLStatement object
b. Using InsertStatement, DeleteStatement or UpdateStatement classes
c. By invoking Insert(), update() and delete() method on a statement object.
d. By invoking the executeInsert(), executeDelete() or executeUpdate() methods of the DMLStatement
e. By invoking the execute() or executeUpdate() method on a statement object

In SQL server, backup of the source data can be created

1. On the same device
2. On another device
3. At some other location

Select one:

a. Only 1
b. All of them
c. Only 3
d. Only 2
e. Both 1 and 2

Consider the following EER diagram.

When the EER model above is mapped to the relational model what would be the primary key of relation 'Bill'?

When the EER model above is mapped to the relational model what would be the primary key of relation 'Bill'?

Select one:

- a. patientID, billNo
- b. patientID, personID
- c. patientID, amount
- d. billNo
- e. billNo, amount

Consider a relation R (A, B, C, D, E, F, G) with the following set of functional dependencies over R:

F = { AB -> CDEFG, D -> B , D-> E , E -> FG}.The corresponding 3rd Normal form relations are.

Select one:

- a. R1 (D, E), R2 (A, B, C, D)
- b. R1 (E, F, G), R2 (D, E), R3 (A, B, C, D)
- c. R1 (A, B, C, D, E, F, G)
- d. R1 (E, F, G), R2 (D, E, B), R3 (A, C, D)
- e. R1 (E, F, G), R2 (A, B, C, D,E)

Search
there are 4 options you can use to map this into an ER,
option 1
Person(SIN,Name)
Student(SIN,GPA)
Teacher(SIN,Salary)
option 2 Since this is a covering relationship, option 2 is not a good match.
Student(SIN,Name,GPA)
Teacher(SIN,Name,Salary)
option 3
Person(SIN,Name,GPA,Salary,Person_Type) person type can be student/teacher
option 4
Person(SIN,Name,GPA,Salary,Student,Teacher) Student and Teacher are bool type fields, it can be yes or no,a good option for overlapping
Since the sub classes don't have much attributes, option 3 and option 4 are better to map this into an ER
